

CAPTURE

Materials such as wood do not suit the use of water to suppress dusts so you must consider alternatives. Capturing the dust as it is released from the material being worked on is the only alternative to water suppression, but this must be done properly.

When purchasing or hiring your tools, consider whether it has the facility to extract dust 'on the tool', as this is the only way you can effectively capture the dusts as they are released. Some tools are fitted with dust bags, but these have only limited efficiency as there is no mechanism to actively suck the dusts out of the tool.

Always try to use a means that will remove the dust by suction.

PROTECT

Even the best control measures aren't going to prevent all dust being released, and it is for this reason that respiratory protective equipment must also be used. Dust masks are graded in three levels - P1, P2, and P3. You should always wear a P3 mask as only these offer the right levels of protection.

Even these aren't infallible so make sure you carry out a face fit test so you can create a tight seal against the face. Beards and stubble simply lift the mask off the face meaning dust can still get round the mask so be aware of this.

REMEMBER!

Exposures to dust won't lead to health problems until later in life. If you protect yourself now then you won't suffer in the coming years, but if you do nothing then by the time you feel the ill health effects it will be too late.

WHAT IS DUST?

Dust can simply be described as particles in the air.

What dust consists of is purely down to what material is being cut, sanded or drilled as the physical action of your tools breaks off small parts of the material into the atmosphere.

The harm that it can do to you depends on what the material is, don't fall into the misconception that all dust does the same thing.

Specific materials which can do particular harm to you are wood, concrete and stone, but other materials have similar potential to harm you and the people around you.

You may well have heard of the terms inhalable and respirable dust before. This is simply a reference to how fine the dust you are breathing in is.

Different materials can affect you in different ways. In the same way the size of the dust can have different effects.

Every effort has been made by HAE/EHA to ensure that the information given in this document and supporting material is accurate and not misleading. HAE/EHA cannot accept responsibility for any loss or liability perceived to have arisen from the use of any such document/material. Only Acts of Parliament and Statutory Instruments have the force of law and only the courts can authoritatively interpret the law.

Any unauthorised reproduction - manually or electronically - is STRICTLY prohibited

Stopping dusts being released should be your priority every time. If there is no dust, then there is no hazard to be exposed to. Damping down your process is the cheapest and most effective way of doing this as wet dusts form a slurry that cannot become airborne. Without any dust in the environment then not only are you reducing what you may breathe in, but you also have the benefit of less cleaning up to do afterwards.

STOP

Whenever you are doing an activity that creates dusts you have an obligation to protect yourself and the others working around you.

WHAT MUST I DO ABOUT IT?

Specific dusts can clog up the pathways in your lung leading to inflammatory responses in the lung, chronic bronchitis or chronic obstructive pulmonary disease (COPD). Around 4,000 people die each year from COPD in the UK from exposures people have had whilst at work. Remember that there is no such thing as general dust; it is always made up of many different compounds. All of these compounds have the potential to do you harm.

When you are breathing in dust that is not wood or silica does that mean its not going to have an effect on you? Non

DUST

used throughout the world, and most commonly we come across it as sand. Because it is so common people regularly disregard the effect it can have on us. The effect of irritation or burns from concrete are something that people working with the material may be familiar with, and this is because they see the effects fairly quickly. The effects of silica exposure are not quick and may take 10 to 30 years to become apparent, but rest assured they can and do arise. Silicosis is a debilitating lung disease that occurs from exposure to silica. There is no cure once it has been diagnosed. It is caused by inhaling the finest silica dust (known as respirable crystalline silica) which is produced when concrete and stone is sanded, cut or drilled with power tools.

Stone and concrete contain a natural compound called silica. Like wood, it is

STONE AND CONCRETE

MDF is an industrially engineered form of wood, made from separated softwood and hardwood fibres. Because of this make up, it has greater potential to form particularly fine dusts when it is cut or worked on. MDF is particularly hazardous because it is made from both softwood and hardwood, and the fine dusts it produces increase the likelihood that dangerous amounts can be breathed in.

MDF

on the type of wood the dust from them can cause allergic reactions or cause cancers in the nose and lungs. Softwood dust is known to cause sensitisation - an allergic reaction, whereas hardwood dust is a known carcinogen. It's vital therefore that you take the right precautions against breathing in these dusts.

Wood dust is a serious problem that people ignore at their peril. Just because it is a natural material that is in use throughout the world many believe that it is not particularly hazardous. Depending

WOOD

It would be very rare for anyone to suffer significant ill health through a single exposure to dust. The ill health symptoms rise from many repeated exposures to small levels of dust. To many people think to themselves, "I'm only doing a quick job" or "what harm could this small bit of work do" and not do anything to protect themselves. It is these little exposures that add up over the months and years to give rise to serious ill health problems. Unfortunately by the time you feel that something is wrong, the ability for the illness to be treated is significantly diminished.

The effects of different dusts is well researched and well known. Unfortunately, the appreciation of this potentially deadly hazard in the workplace takes a back seat to the more visible hazards.

ABOUT IT?

WHY SHOULD I WORRY
